

Data Access and Integrity

Database Connectivity and Access

Authentication vs. Authorization

- ▶ Authentication – Who are you?
- ▶ Authorization – What can you do?

Authentication

- ▶ Good authentication requires all three of:
 - ▶ Something you know (e.g., password)
 - ▶ Something you have (e.g., dongle, cryptographic key)
 - ▶ Something about you (e.g., fingerprint, other biometric)
- ▶ Id and password
 - ▶ How good is this?
- ▶ One time password (OTP)

Authentication

- ▶ Who does authentication?
 - ▶ Application
 - ▶ “System”

Authorization

- ▶ Authorization can be determined at different levels
- ▶ Database level
 - ▶ Use of GRANT statement
 - ▶ DBA will assign access to users at database level
 - ▶ We have to understand the *role to resource* assignments for users
- ▶ Application-level
 - ▶ Application has an id(s) to access database
 - ▶ Developer (via biz rules) will assign access at application level
 - ▶ Use of WHERE clause

Application-Level Authorization

- ▶ Varied means of accomplishing authorization
 - ▶ Application-level
 - ▶ Username, password provided to application
 - ▶ All users interact with application in same way
 - ▶ This approach is frowned upon (effectively sharing a password)
 - ▶ User-level
 - ▶ Username, password provided to user
 - ▶ More complex but more common

Task-Level Authorization

▶ What can the user do?

▶ Task-Based

- ▶ Very granular
- ▶ User is assigned (or not) permission to each and every task
 - ☐ May include read/write/create distinction
- ▶ Difficult to maintain
 - ☐ Can create features to make it easier

Application-Level Authorization

▶ Role-Based

- ▶ Username, password provided to user
- ▶ Each user is assigned a role which in turn has certain privileges associated with it
- ▶ Typical roles:
 - ▶ Admin
 - ▶ Editor
 - ▶ General User
 - ▶ Public

Application-Level Authorization

▶ Code considerations

- ▶ Must ask the question:

Is the user authorized to perform this task?

- ▶ Who is the user?
- ▶ What are their rights?
- ▶ Can they do this task?
- ▶ What if they can't?
 - ▶ How did they get this far?
 - ▶ Why did they get this far?

Business Rules

- ▶ Who
- ▶ What
- ▶ When
- ▶ From Where

Checking Authorization

▶ Method 1

- ▶ Determine user
- ▶ Query database for user access rights
- ▶ Check rights against requested action

▶ Method 2

- ▶ Issue user “ticket” upon login
- ▶ Check “ticket” for user access rights
- ▶ Check rights against requested action

Tokens

- ▶ What is a token?
- ▶ Hash
 - ▶ One-way access only
 - ▶ Very secure
 - ▶ Salt: fixed or variable
 - ▶ Iteration count
- ▶ Encryption
 - ▶ Two-way Access
 - ▶ Embedded info
 - ▶ Less secure, but more useful?

Credential Storage

- ▶ User credentials
 - ▶ OS service
 - ▶ Application
- ▶ Application credentials
 - ▶ Code
 - ▶ File

SOA Considerations

- ▶ Where are authentication and authorization determined?
- ▶ Is one token passed through or are multiple tokens used?
- ▶ What about multiple business layers?

Auditing the Database

- ▶ Tracking activity can be as important as data itself
 - ▶ Connections, queries, errors, performance...
- ▶ Important for record keeping
 - ▶ What was the change?
 - ▶ Who made the change?
 - ▶ Why was the change made?
 - ▶ When was the change made?
 - ▶ How was the change made?
- ▶ May be logged to the same or another table

Auditing the Database

- ▶ Auditing types

- ▶ “Snapshot”

- ▶ Use fields in each table to record critical information

- ▶ “full” audit trail

- ▶ Use a separate table to store old and new information as well as metadata about the change

Data Integrity

- ▶ Garbage in = Garbage out
- ▶ Aggregating can be made difficult or impossible
 - ▶ And cleansing is expensive!
- ▶ RIT can be written as:
 - ▶ “RI ofT”
 - ▶ “Rochester Institute of Technology”
 - ▶ “Roch. Inst. Of Tech.”
 - ▶ “Rochester Inst. Of Tech.”
 - ▶ Etc.

Form Validation

- ▶ Make data field do the work!
- ▶ Can be encouraged:
 - ▶ Appropriate form controls
- ▶ Can be enforced:
 - ▶ At query submission
 - ▶ At form processing
 - ▶ At information entry
 - ▶ At form construction

Handling Data Modification

- ▶ Must ensure data consistency, referential integrity
- ▶ Cascading of actions
 - ▶ Programmatically or at database level
 - ▶ Nullification or deletion of children
- ▶ Recall discussion on proper *deletion!*

Double Entry Systems

- ▶ Accuracy of inserted data may be critical
- ▶ What if data is free-form and not easily tested?
- ▶ Enter the data twice!
 - ▶ Operator A enters data
 - ▶ Status flag set to Hold
 - ▶ Operator B enters data
 - ▶ Data is compared
 - Adjusted (if necessary) and saved
 - Status flag set to Confirmed
